

COMP90054 – Week 6 tutorial

Prepared by Zijie Xu. Last updated: 30 August 2023

Delete relaxation

Objective

- Find an estimate of the perfect heuristic h^* for any STRIPS problem \mathcal{P}

Delete relaxation

- Idea: Removing all delete effects of the operators
 - “What was once true remains true forever”
 - State dominance: $s' \supseteq s \rightarrow s'$ dominates s
- Super script “+” \rightarrow delete relaxed

where, for all $\Pi \in \mathcal{P}$, $h^*(r(\Pi)) \leq h^*(\Pi)$.

For $h^+ = h^* \circ r$:

- Problem \mathcal{P} : All STRIPS planning tasks.
- Simpler problem \mathcal{P}' : All STRIPS planning tasks with empty deletes.
- Perfect heuristic h'^* for \mathcal{P}' : Optimal plan cost = h^* on \mathcal{P}' .
- Transformation r : Drop the deletes.
- \rightarrow Is this a native relaxation? Yes.
- \rightarrow Is this relaxation efficiently constructible? Yes.
- \rightarrow Is this relaxation efficiently computable? No.

- h^+ is the optimal delete relaxation heuristics (cost of an optimal relaxed plan)
- Delete relaxation is admissible, so can use h^+ to estimate h^*
- Optimal delete relaxed planning is NP-complete, so it is hard to find h^+

Delete and precondition relaxation

- Relaxed problem does not care about preconditions and deletes
- $h^{\text{pre\&del}}$, as the optimal pre&del relaxation heuristics, is admissible, so can use $h^{\text{pre\&del}}$ to estimate h^*
- Optimal pre&del relaxed planning is NP-complete (subset sum problem), so it is hard to find $h^{\text{pre\&del}}$
- Can use $h^{\text{goal count}}$ to estimate $h^{\text{pre\&del}}$, but it is neither admissible nor consistent
 - Action cost $< 1 \rightarrow$ inadmissible
 - One cost action achieving two goals \rightarrow inconsistent

Estimate h^+

- $h(s, g)$ estimates the cost of making all propositions $p \in g$ true at state s
 - The original representation $h(s)$ is essentially $h(s, G)$

Definition (h^{add}). Let $\Pi = (F, A, c, I, G)$ be a STRIPS planning task. The *additive heuristic* h^{add} for Π is the function $h^{\text{add}}(s) := h^{\text{add}}(s, G)$ where $h^{\text{add}}(s, g)$ is the point-wise greatest function that satisfies $h^{\text{add}}(s, g) =$

$$\begin{cases} 0 & g \subseteq s \\ \min_{a \in A, g \in \text{add}_a} c(a) + h^{\text{add}}(s, \text{pre}_a) & |g| = 1 \\ \sum_{g' \in g} h^{\text{add}}(s, \{g'\}) & |g| > 1 \end{cases}$$

Definition (h^{max}). Let $\Pi = (F, A, c, I, G)$ be a STRIPS planning task. The *max heuristic* h^{max} for Π is the function $h^{\text{max}}(s) := h^{\text{max}}(s, G)$ where $h^{\text{max}}(s, g)$ is the point-wise greatest function that satisfies $h^{\text{max}}(s, g) =$

$$\begin{cases} 0 & g \subseteq s \\ \min_{a \in A, g \in \text{add}_a} c(a) + h^{\text{max}}(s, \text{pre}_a) & |g| = 1 \\ \max_{g' \in g} h^{\text{max}}(s, \{g'\}) & |g| > 1 \end{cases}$$

- Two ways to estimate h^+ : h^{add} and h^{max}
 - h^{add} sums up the cost of all singleton sub-goals as an estimate
 - h^{max} uses the costliest sub-goal as an estimate
- h^{max} is optimistic: $h^{\text{max}} \leq h^+ \leq h^*$
 - h^{max} is admissible, but the estimate can be too small
- h^{add} is pessimistic: $h^{\text{add}} \geq h^+$, so $\exists \Pi, s$ such that $h^{\text{add}}(s) > h^*(s)$
 - h^{add} yields larger estimate, but no guarantee on admissibility
- Use Bellman-Ford algorithm to calculate h^{add} and h^{max} (the table method)

Bellman-Ford variant computing h^{add} for state s

```

new table  $T_0^{\text{add}}(g)$ , for  $g \in F$ 
For all  $g \in F$ :  $T_0^{\text{add}}(g) := \begin{cases} 0 & g \in s \\ \infty & \text{otherwise} \end{cases}$ 

fn  $c_i(g) := \begin{cases} T_i^{\text{add}}(g) & |g| = 1 \\ \sum_{g' \in g} T_i^{\text{add}}(g') & |g| > 1 \end{cases}$ 

fn  $f_i(g) := \min[c_i(g), \min_{a \in A, g \in \text{add}_a} c(a) + c_i(\text{pre}_a)]$ 
do forever:
  new table  $T_{i+1}^{\text{add}}(g)$ , for  $g \in F$ 
  For all  $g \in F$ :  $T_{i+1}^{\text{add}}(g) := f_i(g)$ 
  if  $T_{i+1}^{\text{add}} = T_i^{\text{add}}$  then stop endif
   $i := i + 1$ 
enddo

```

- Swap $\sum_{g' \in g}$ for $\max_{g' \in g}$ in $c_i(g)$ to compute h^{max}

Logistics example from lecture

- Initial state $I: t(A), p(C)$.
- Goal $G: t(A), p(D)$.
- Actions $A: dr(X, Y), lo(X), ul(X)$.

Content of Tables T_i^{add} : (Table content T_i^1 , where different, given in red)

i	$t(A)$	$t(B)$	$t(C)$	$t(D)$	$p(T)$	$p(A)$	$p(B)$	$p(C)$	$p(D)$
0	0	∞	∞	∞	∞	∞	∞	0	∞
1	0	1	∞	∞	∞	∞	∞	0	∞
2	0	1	2	∞	∞	∞	∞	0	∞
3	0	1	2	3	3	∞	∞	0	∞
4	0	1	2	3	3	4	5 (4)	0	7 (4)
5	0	1	2	3	3	4	5 (4)	0	7 (4)

h^{add}

- [0] Initial state: $t(A), p(C)$
- [1] $t(B): dr(A,B) + \text{sum}(T_0(t(A))) \rightarrow 1 + 0 = 1$
- [2] $t(C): dr(B,C) + \text{sum}(T_1(t(B))) \rightarrow 1 + 1 = 2$
- [3] $t(D): dr(C,D) + \text{sum}(T_2(t(C))) \rightarrow 1 + (2 + 0) = 3$
 $p(T): \text{load} + \text{sum}(T_2(t(C)) + T_2(p(C))) \rightarrow 1 + (2 + 0) = 3$
- [4] $p(A): \text{unload} + \text{sum}(T_3(t(A)) + T_3(p(T))) \rightarrow 1 + (0 + 3) = 4$
 $p(B): \text{unload} + \text{sum}(T_3(t(B)) + T_3(p(T))) \rightarrow 1 + (1 + 3) = 5$
 $p(D): \text{unload} + \text{sum}(T_3(t(D)) + T_3(p(T))) \rightarrow 1 + (3 + 3) = 7$

h^{max}

- [0] Initial state: $t(A), p(C)$
- [1] $t(B): dr(A,B) + \text{max}(T_0(t(A))) \rightarrow 1 + 0 = 1$
- [2] $t(C): dr(B,C) + \text{max}(T_1(t(B))) \rightarrow 1 + 1 = 2$
- [3] $t(D): dr(C,D) + \text{max}(T_2(t(C))) \rightarrow 1 + \text{max}(2, 0) = 3$
 $p(T): \text{load} + \text{max}(T_2(t(C)) + T_2(p(C))) \rightarrow 1 + \text{max}(2, 0) = 3$
- [4] $p(A): \text{unload} + \text{max}(T_3(t(A)) + T_3(p(T))) \rightarrow 1 + \text{max}(0, 3) = 4$
 $p(B): \text{unload} + \text{max}(T_3(t(B)) + T_3(p(T))) \rightarrow 1 + \text{max}(1, 3) = 4$
 $p(D): \text{unload} + \text{max}(T_3(t(D)) + T_3(p(T))) \rightarrow 1 + \text{max}(3, 3) = 4$
